

Analytical Derivation of Electron Mass from Electromagnetic Self-Energy

Unified Biquaternion Theory Team

August 9, 2025

Overview

In this document, we analytically derive the electron mass from its electromagnetic self-energy, based on the hypothesis that the electron is a topological excitation of the Θ_1 field.

Assumptions and Ansatz

We assume that the charge distribution of the electron is spherically symmetric and approximated by a Gaussian:

$$\rho(r) = \frac{e}{\pi^{3/2} R^3} \exp\left(-\frac{r^2}{R^2}\right)$$

This allows analytical treatment and captures the finite localization scale of the electron.

Electrostatic Potential

The electrostatic potential $\phi(r)$ is given by solving Poisson's equation:

$$\phi(r) = \frac{1}{4\pi\epsilon_0} \int \frac{\rho(r')}{|\vec{r} - \vec{r}'|} d^3r'$$

For the Gaussian source, this results in:

$$\phi(r) = \frac{e}{4\pi\epsilon_0 r} \operatorname{erf}\left(\frac{r}{R}\right)$$

Self-Energy Integral

The total electromagnetic self-energy is:

$$\delta m_e c^2 = \frac{1}{2} \int \rho(r) \phi(r) d^3r$$

Evaluating the integral yields:

$$\delta m_e = \frac{e^2}{\sqrt{\pi\epsilon_0} R c^2}$$

Interpretation

This result links the electron mass to the scale R of its internal structure, with no new parameters introduced. The remaining task is to derive R from the stress-energy distribution of the Θ_1 Hopfion solution.
